Abstract

NenuFAR is both a giant extension of the LOFAR and a large standalone instrument in the low-frequency range (10-85 MHz). It was designed in Nançay with national and international collaboration. Antennas radiators were modeled on the LWA antenna design whereas preamplifiers were designed in France. Antennas will be distributed in 96 mini-arrays of 19 dual-polarized elements, densely covering a disk of 400 m in diameter. A few mini-arrays are expected to lie at distances of 2-3 km. A silent control-command system was designed, and the computer dialog with LOFAR defined. Receivers will include the LOFAR backend, a local beamformer and a local correlator. NenuFAR is in construction in Nançay and it was recently granted by the SKA office the official label of SKA pathfinder. Its exploitation will expand the scope of LOFAR scientific studies as well as permit new studies, preparing for SKA science. NenuFAR concept has many points in common with GURT (the Giant Ukrainian Radio Telescope), with which it shares some technical studies, as its exploitation will benefit from a coordination with UTR-2. We describe the instrument, technical developments and science case.

Keywords: Radio astronomy; radio telescope; antenna array; antenna effective area.

1. INTRODUCTION

LOFAR is the new European multi-scale low-frequency (LF) radio interferometer in the range 30-250 MHz with baselines from ~50 m to ~1000 km [1]. The constitutive elements of LOFAR are phased arrays or “stations” distributed in the Netherlands and surrounding European countries. One of these stations, FR606, is installed in the Nançay radio observatory (France). Each station consists of two arrays of antennas and a “back-end” that preprocesses antenna signals (filtering, digitization, spectral channelization and beamforming). Preprocessed digital data are then sent at ~3 Gbits/sec to the central computer (in Groningen, NL) that performs the correlations per interferometric baseline and/or final pencil beamforming. The Low-Band Antenna (LBA) array covers the range 30-80 MHz and consists of 96 elementary crossed dipoles in international stations such as FR606 (48 in Dutch stations). The High-Band Antenna (HBA) array covers the range 110-250 MHz and consists of 96 “tiles” of 16 analog-phased crossed dipoles (2×24 in Dutch stations). At any given time, the backend can be connected to either the LBA or the HBA (not both simultaneously). A third input to the backend exists, that was initially planned for an LBL (Low-Band Low, 10-50 MHz) array that never existed due to limited funding.

NenuFAR (formerly “LSS” for “LOFAR Super Station”) exploits the availability of the third analog input of the LOFAR back-end to form a new LF phased array interferometer. No a priori constraints exist on its design and it will be fully compatible with LOFAR operations in the LBA band (i.e. that can be correlated with LBA arrays of other LOFAR stations, instead of the FR606 LBA array) and at the same time provide a considerably increased instantaneous sensitivity and frequency coverage.

2. TECHNICAL DESCRIPTION OF NENUFAR

NenuFAR possesses a hierarchical design inspired of the HBA antenna field but adapted to a lower frequency band, which extend the LBA band (e.g. ~10-90 MHz). The NenuFAR “tile” is composed of adapted dual-polarization antennas which signal is locally combined as a small phased array. Each tile provides a large gain from 10-15 MHz to 85-87 MHz (i.e. a ratio f_{\max} / f_{\min} double of that of the LBA range). Their output is a pair (for the two linear polarizations) of analog signals that enters either the LBL analog inputs on the FR606 back-end or the analog input of a dedicated back-end installed close-by. The three main levels of the instrument drove three different design studies:

- The design of the antenna (feed and preamplifier)

- The distribution inside the LF “tile” or “mini-array” (the number, distribution of antennas and the phasing system)
- The distribution of these mini-arrays on the Nançay field (optimal for phased-array or interferometer performance vs. site constraints).

A lot of effort has also been put in the design of a prototype receiver for the three first prototypes of mini-arrays.

2.1. ANTENNA AND PREAMPLIFIER

The diagram of the antenna radiator was optimized via electromagnetic simulations with the NEC code and validated with tests on the sky; optimized parameters include a broad and smooth beam (nearly isotropic, albeit with extinction below 20° elevation) and maximum efficiency (related to electrical and ground losses), over a large frequency bandwidth; this implies an antenna radiation resistance and (low) reactance as constant as possible over the band of interest and versus time; cost effectiveness and compatibility with LOFAR strongly favored linearly polarized crossed dipoles; the optimal compromise is a “thick” inverted-V dipole similar to the LWA Fork (see Fig.1), with a metallic ground screen [2].

Three designs have been studied and realized for the antenna preamplifier, which is a key element for the antenna gain and its susceptibility to radio-frequency interference (RFI): (1) the “GURT2” design from the Institute of Radio Astronomy, Kharkiv, Ukraine, (2) the Subatech/Nançay design, and (3) the Nançay microelectronics laboratory design. (1) is based on discrete components, whereas (2) & (3) are based on ASIC circuits. All have good characteristics, with a noise ~10 dB below the sky noise level. For NenuFAR-1, the Subatech/Nançay design was selected.

2.2. THE MINI-ARRAY

The number of antennas within each tile should be of the order of 16 (again as in HBA tiles) in order to provide at least an order of magnitude increase of the instantaneous sensitivity. The antenna distribution within each LF tile was optimized for a low side lobe level and a large field of view symmetrical around the zenith; in [3] it is found that a distribution with a central antenna surrounded by two circular rings of antennas meets these requirements, especially if the rings have different (or no) symmetry axes, i.e. if the global distribution cannot be superposed to itself by a rotation $< 2\pi$. In parallel, we have calculated that analog phasing of each LF tile using 7-bit delay lines (cable lengths) allows to perform achromatic phasing over the whole NenuFAR band (10-87 MHz) with gain variations <10% across the beam, and provide one input per polarization to the backend. In order to be cost-effective, delay lines must be mutualized for groups of antennas, e.g. by arranging antennas with a

Fig. 1. Picture of the prototype mini-array.

regular spacing in two orthogonal directions. Taking into account this constraint we modified the above optimized antenna distributions to obtain an LF Mini-array LSS tile of 19 antennas (a central one surrounded by an hexagon of 6 antennas and a second one of 12 antennas, or equivalently regular lines of 3 / 4 / 5 / 4 / 3 antennas with each line shifted by 1/2 inter-antenna spacing relative to its neighbors (Fig.2). The absolute value of inter-antenna spacing was set to 5.5 m in order to maximize the effective area without overlap at LF, while keeping the NenuFAR extent compatible with its hosting at the Nançay station. The instantaneous LF tile beam will have an angular size of 10° to 50° over the NenuFAR spectral range (~25° at 30 MHz).

Fig. 2. Schematic layout of the mini-array

2.3. NENUFAR AS AN INTERFEROMETER / PHASED ARRAY

The 96 tiles should be arranged in a relatively dense layout (within a few hundred meters diameter), providing a smooth overall beam with a low side lobe level and compatible with the available land in an observatory such as the Nançay station, and at the same time minimize the overlap between antennas

effective areas in order to maximize the NenuFAR sensitivity.

The optimal distribution of the 96 LF tiles was computed using the algorithm [4], taking into account a “site mask” of the Nançay station including its limits and forbidden areas (the station FR606 itself and other antennas of the site). It provides a smooth, Gaussian distribution of visibilities in the (u,v) plane, and thus a near-Gaussian NenuFAR beam pattern. The layout of trenches and cables connecting the LF tiles to the FR606 backend was optimized using a reasonable cost ratio per unit length of trench/cable in input to a specific optimization algorithm [5]. The obtained LF tiles distribution and layout is displayed in Fig.3. It implies a NenuFAR beam size of 0.5°-3° (~1.5° at 30 MHz). In order to reduce the side lobe level resulting from the regular antennas arrangement in the LF tiles, each tile will be rotated by a random amount with respect to each other, but all crossed dipoles within all tiles will be oriented along the same directions, at 45° from the meridian.

Fig. 3. Distribution of the 96 mini-arrays around the LOFAR station FR606 in Nançay.

3. NENUFAR PERFORMANCE AND OBSERVING MODE

3.1. OBSERVING CAPABILITIES AND IMPROVEMENTS BROUGHT BY NENUFAR

NenuFAR by itself, is not a powerful imaging instrument, but its collecting area, and thus its sensitivity, will bring several significant improvements to LOFAR:

- The long LOFAR baselines including the NenuFAR will be ~ 19 times more sensitive than long baselines between two LBA arrays; as the available radio power corresponding to one angular details is generally weak, this increased sensitivity will give access to an increased number of calibrators (typically ~ 10) in the vicinity of the studied target; this will improve LOFAR's capabilities for high resolution imaging in the LBA range.
- By adding $96 \times 19 = 1824$ antennas to the present 2700 LOFAR LBA antennas, the NenuFAR will almost double LOFAR's sensitivity in the LBA imaging mode.
- When most of the “core” (closely-packed) LOFAR stations will be used for time-demanding projects such as observing the Epoch of Reionization (EoR), the NenuFAR will provide an alternative core and, by correlation with the “remote” LBA arrays, will preserve good imaging capability in parallel with the above projects; provided that the central correlator can handle two streams of data from two LOFAR sub-arrays (namely the core, and the NenuFAR + remote stations) the NenuFAR will improve LOFAR-LBA imaging capabilities for a significant fraction of the time.
- Correlation of signals from the LF tiles within the NenuFAR will provide sensitive baselines 2 to 3 times shorter than a LOFAR station diameter - the shortest baseline presently available, permitting to image large-scale structures, larger than an instantaneous station beam ($\sim 10^\circ$ at 30 MHz); short baselines are presently available by correlation of LBA antennas within a station, but with much lower sensitivity.
- The NenuFAR will also be a very large standalone instrument: it will have an effective area (and thus sensitivity) ~ 19 times larger than the LBA array of an international station, i.e. $<70\%$ to 85% of all LOFAR-LBA arrays, but this area will be instantaneously and fully available during use, especially in coherent tied-array (or phased-array) beam mode (TAB); by contrast, the coherent phasing of LOFAR-LBA array signals is limited to the 24 core stations that share the same reference clock (and have the same ionosphere above them); thus, the instantaneous sensitivity of the NenuFAR in coherent TAB mode will be 1.6 times better than the LOFAR-LBA one (Fig.4).

- Finally, in standalone mode, the NenuFAR will extend the observation bandwidth to significantly lower frequencies than the LBA range.

Fig. 4. Theoretical absolute (a) and relative (b) effective collecting areas of NenuFAR between 15 and 80 MHz for NenuFAR (NenuFAR), the full LOFAR-LBA, the LOFAR core only and a typical 300m-diameter dish radio telescope (Arecibo).

The NenuFAR pointing will be controlled by a dedicated LCU (Local Command Unit) connected to 96 electronic modules, one in each LF tile, specifying the phasing scheme to be applied at any given time (different for each LF tile due to their random rotations); these modules are designed to be completely “radio-quiet” outside pointing time; pointing will occur at intervals from 20 to 60 sec, ensuring low gain variation in the main beam direction. The NenuFAR LCU will be connected to the LOFAR LCU of station FR606. When NenuFAR will be used jointly with other LOFAR LBA arrays (so-called “International” mode), pointing orders will come from the LOFAR operations center via the LOFAR LCU and be translated into LF tiles phasing commands by the NenuFAR LCU; data recorded by the LOFAR backend will be sent to the LOFAR central correlator. In “Stand-alone” mode, pointing orders will come from a local command computer, and the data will be recorded locally.

3.2. STANDALONE USE WITH DEDICATED RECEIVER

The standard NenuFAR concept consists of the 96 additional LF tiles and their phasing and command system, that are connected to the LOFAR backend of FR606. The contract of any European station owner with the International LOFAR Telescope board includes the right to use that station in standalone mode for ~10% of the time. As the standard LOFAR station backend only allows to record low frequency-time resolutions observations (typically in 200 kHz in 1 sec bins), the full scientific exploitation of standalone NenuFAR observations requires either LOFAR's "Single Station" mode or a dedicated post-backend [6]. The former consists of a sub-array formed by a single station, which high-resolution data are sent to the central correlator for processing as TAB data. The latter is for example the ARTEMIS (Advanced Radio Transient Event Monitor and Identification System) post-backend dedicated to transients detection and study, that ingests high resolution station data and locally computes high-resolution time-frequency planes including parametric dedispersion [7].

If one wants to compute locally more than time-frequency planes with NenuFAR standalone data (e.g. auto- and cross-correlations of tile signals), then a dedicated receiver is necessary. Such a dedicated receiver has been studied in the frame of the NenuFAR design study. It will consist of either a post-LOFAR-backend (ARTEMIS-like), or a fully independent backend. The LOFAR backend digitizes the LBA or NenuFAR tile signals, channelizes it in 200 kHz bands (called "subbands"), and computes beamforming within each subband. The beamformed signal of 244 subbands is sent to the LOFAR central correlator. The latter further channelizes (down to 0.76 kHz resolution) the signals of all subbands from all stations, and computes auto-/cross-correlations and/or incoherent or coherent (adequately time-shifted) summation in order to produced polarized images and/or TAB data.

A post-LOFAR-backend dedicated receiver would ingest locally the station products (as does ARTEMIS) and channelize, auto-/cross-correlate, and integrate them. A fully independent backend would perform the tasks of both the LOFAR backend and the central correlator, but in an optimized integrated way. A large computing power is required, but a preliminary design study suggests that this is within the scope of new generation FPGAs. Additional "intelligent" processing like RFI mitigation or parametric dedispersion could be included. Transient Buffer Board data will also be processed in all cases. A dedicated receiver is important not only because it allows local, flexible processing, but primarily because it will greatly increase the duty-cycle of the NenuFAR standalone use beyond the "guaranteed" 10% fraction of the time, albeit with some pointing constraints. With a post-LOFAR-backend receiver, usable in parallel to all NenuFAR observations (standalone or in

correlation with LOFAR LBA), the standalone analysis of NenuFAR data will be possible 100% of the time during which the NenuFAR tiles are connected to the FR606 backend, but the target will necessarily be within the 0.5°-3° NenuFAR beam fixed by the current LOFAR observation program. Conversely, with a fully independent backend that would process NenuFAR data in parallel with the standard station backend, standalone mode becomes possible 100% of the time, whatever array (LBA, HBA or NenuFAR) is connected to the LOFAR backend. The only pointing constraint of this standalone NenuFAR mode is that the target must be located within the 10°-50° analog LF tile beam.

4. NENUFAR-1 & PATH TO THE FULL NENUFAR

The final distribution of the 96 mini-arrays was set by the positioning constraints around the FR606 station and the power distribution over the entire field. NenuFAR was divided in "petals" allowing a modular and flexible implantation of the instrument. Starting from the three prototype mini-arrays that were built during the design study, ~1/4 of the instrument (in fact 26 mini-arrays, defined as "NenuFAR-1") is planned to be built before early 2015. The chosen mini-arrays provide a decent instrument PSF that will improve gradually with the construction of additional petals of the array while keeping the best azimuthal symmetry of the mini-array distribution (and therefore, the azimuthal symmetry of the instrumental beam and interferometric coverage).

The expected performance of NenuFAR is compared to that of LOFAR in Fig.4 and a summary table of the instrumental characteristics, compared to other classical radio instrument can be found in Table 1. The expected sensitivities (for a 8-hour time integration over the ~10-90 MHz) are 120-240 mJy for NenuFAR-1, 50-100 mJy for the whole NenuFAR.

5. CONCLUSION

The NenuFAR characteristics are compared to those of other existing international instruments in Table 1. In the European context, several instrumental projects are developed by LOFAR participants, such as ARTEMIS (from Oxford Univ., see above) or AART-FAAC (from Univ. Amsterdam – it aims at cross-correlating the 288 LBA and HBA signals from the 6 central LOFAR stations to perform permanent all-sky monitoring [8]).

NenuFAR is a LOFAR extension and a standalone instrument with emphasis on very high instantaneous sensitivity. We foresee it as an "Arecibo in Nançay". It is also a SKA precursor for the French community, both scientific and technical (for SKA-low).

It is interesting also the operation of NenuFAR for the Universe studies in coordination with another ground-based and space low frequency instruments such as UTR-2, URAN, GURT, NDA, NRT, LOFAR,
